

Contribution

We validate the results of leverage based sampling for LS-regression, shown by Ma et al. [1]. We explore the possibility of using the leverage based sampling distribution from LS-regression on 2 class classification, and introduce two new approaches for sampling form an leverage distribution (important points).

Motivation

The importance of sampling methods are initiated by very large datasets where it is not feasible to use all of the available data. This is illustrated by the rise in online access to video data. These data contain many frames that are basically the same and therefore redundant.

- Research Questions**
- Will the regression based sampling distribution improve our performance in classification?
 - Can leverage based sampling be generalized to classification?

Sensitivity Based Distribution

We wish to find the effect that a datapoint's class has on the predicted class for that datapoint.

$$\frac{\delta \hat{Y}_n}{\delta Y_n} \tag{1}$$

Our prediction is

$$\hat{Y}_n = p(y|\bar{x}, \bar{w}) \quad \bar{w} \text{ s.t. } \frac{\delta L}{\delta \bar{w}} = 0 \tag{2}$$

Since 2 depends both directly and indirectly on y we see that

$$\begin{aligned} \frac{\delta}{\delta y} \frac{\delta L}{\delta \bar{w}} &= 0 \\ \Downarrow \\ \frac{\delta^2 L}{\delta y \delta \bar{w}} + \frac{\delta^2 L}{\delta \bar{w} \delta \bar{w}^T} \frac{\delta \bar{w}}{\delta y} &= 0 \end{aligned}$$

and from this we can get our leverage score (1)

$$\frac{\delta p(y|\bar{x}_n, \bar{w})}{\delta \bar{w}^T} \frac{\delta \bar{w}}{\delta y} = - \frac{\delta p(y|\bar{x}_n, \bar{w})}{\delta \bar{w}^T} \left[\frac{\delta^2 L}{\delta \bar{w} \delta \bar{w}^T} \right]^{-1} \frac{\delta^2 L}{\delta y \delta \bar{w}} \tag{3}$$

Uncertainty Based Distribution

bla

Conclusion

itr doesnt work because the classification doesnt gain much from the collective distribution of both classes.
